

# QCOMPPW100: Quantum computing kickoff practical work

*Lotus Noir* Quantum Computing Research Group

Based on:

MITx: 8.370.1x Quantum Information Science I, Part I

**Practical work Outline:** During This practical work we will simulate a quantum computer

## Contents

| 6.2      | Quantum computer                                  | 3        |

## 1 Generate state vector

Program the function `getStateVector`. This function takes in input, the two integers: `nbQbit` and `state`. This function output a vector of  $2^{nbQbit}$  values, with the value  $state^{th}$  value being equal to one and the other values must be equal to zeroes. This function must pass this test:

```
nbQbit = 3
state = 5
assert(str(getStateVector(nbQbit, state)) == "[0,0,0,0,0,1,0,0]")
```

## 2 compute matrix thanks to kronecker product

Program the function `computeMatrix`. This function takes in input an integers : `nbQbit`, a 2x2 matrix of complex number: `matrix`, and an integer `fQbit`. This function output:  $I_2^{\otimes fQbit} \otimes matrix$ . This function must pass this test:

```
nbQbit = 2
matrix = np.array([[0,1],[1,0]])
fQbit = 1
assert(str(computeMatrix(nbQbit, matrix, fQbit)) == "" "[0. 1. 0. 0.]
[1. 0. 0. 0.]
[0. 0. 0. 1.]
[0. 0. 1. 0.]] """)
```

## 3 compute CNOT

Program the function `computeCNOT`. This function takes in input an integers: `nbQbit`, an integers `fQbit` and integer `sQbit`. This function must output a such kronecker product:  $I_2^{\otimes fQbit} \otimes CNOT$ .

## 4 compute product

Program the function `computeProduct`. This function takes in input this array `Matrixs` of square matrixs of the same dimension. This function must output their product. This function must pass this test:

## 5 compute Probability

Program the function `computeProbability`. This function takes in inputs an array of complex number: `tab`. This function output an array of the same dimension. Every coefficient of the output is computed this way:

$$output[i] = \frac{|tab[i]|^2}{\sum_{k=0}^{tab.length()-1} |tab[k]|^2}$$

## 6 package everything

### 6.1 Quantum gates

Program the class `quantum gates`

## 6.2 Quantum computer

Program the function `quantumCComputer`, that takes in input an integers: `nbQbit`, array of integer having on value at 0 and every other values at one: `input` and an array of `QuantumGate`: `quantumGates`. This function must output the computed probability of the product of the input and the product of all this  $nQbit \times nqBit$  matrices create from the quantum gates.

This function must pass this test
